(Bulletin of the Ac.Sc., Geophysics Series), 1957, No.3,  
pp.401-403 (U.S.S.R.)

ABSTRACT: Numerous methods of ore prospecting by means of alternating currents of various frequencies are based on the assumption that the electric and magnetic characteristics of the rocks, and particularly the electric resistance, are independent of the frequency. Laboratory investigations on this point are contradictory. In this paper the results are described of field investigations of the dependence of the specific resistance on the frequency between 0.3 and 300 c.p.s. The experiments were made with a current of periodic but not of sinusoidal shape.

TITLE: Method of Interpretation of the Curves of Electromagnetic Sounding (~~Metodika interpretatsii krivyykh elektromagnitnykh zondirovaniy~~)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya, 1957, No.12, pp. 1515 - 1519 (USSR).

ABSTRACT: Under the direction of A.N. Tikhonov, the method of electro-magnetic sounding is being developed in the Institute of Physics of the Earth Ac.Sc. USSR (Institut Fiziki Zemli AN SSSR) for the purpose of geological prospecting. The obtained experimental material is described in a separate report by the author of this paper, Ye.M. Ushakov and others - "Development of the Technique of Sounding by Means of Alternating Currents and Study of the Resolution Power of this Type of Prospecting", Institute of Physics of the Earth, 1956. On the basis of analysis of some of the obtained results, it is concluded that sounding with direct current effected by means of a system of spacings between the metering circuits can be substituted by frequency-sounding effected solely with a single spacing between the metering instruments. The possibility of using frequency-sounding is based on obvious physical considerations and has been confirmed by various authors,

Card1/2

Method of Interpretation of the Curves of Electro-magnetic Sounding. 49-12-11/16

e.g. A. Krayev and V.R. Zatsepin [Ref.3] and M. Miller [Ref.4]. However, so far, the necessary data permitting conclusions on the quantitative potentialities of the frequency-sounding have not been obtained. Only the right branch of the frequency-sounding  $E_x$  or  $E_z$  is applied and, knowing the value of  $\rho_1$ , it is possible to determine the thickness of the sedimentary complex of rocks by means of dipole electric sounding. There are 5 figures and 4 references, 3 of which are Slavic.

TITLE: ~~Some~~ Results of Electromagnetic Sounding of Geological Structures (Nekotoryye rezul'taty elektromagnitnogo zondirovaniya geologicheskikh struktur)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya, 1958, Nr 1, pp.136-137 (USSR)

ABSTRACT: Some of the results are given which were obtained in electromagnetic sounding of geomagnetic structures located underneath intermediate nonconducting strata. The geoelectric structure of the points at which the investigations were carried out was determined according to the data of supporting wells and according to soundings by means of direct current carried out by various teams of Glavneftgeofizika. The soundings described in the paper were obtained in the neighbourhood of the supporting wells. The geological conditions of the point are briefly described. There are 2 graphs and 1 Russian reference.

Ed.: A.G. Kalashnikov, Professor; Ed. of Publishing House: Ye.B. Kuznetsova;  
Tech. Ed.: Yu.V. Rykina.

PURPOSE: The publication is intended for geophysicists and geologists, particularly  
for those interested in the geological structure of Western Siberia from the  
point of view of oil and natural gas deposits.

COVERAGE: This is a symposium of four articles published by the Institute of  
Physics of the Earth of the Academy of Sciences USSR. The articles deal mainly  
with geological prospecting in Western Siberia for oil and natural gas by using  
geophysical methods, such as electrical sounding and investigation of gravita-  
tional fields. References (all Soviet) are given at the end of each article.

TITLE: Calculation of the Commutating Capacitance and Cathode Inductance of a Parallel Inverter with Resistive Load

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Energetika i avtomatika, 1959, Nr 5, pp 194-196 (USSR)

ABSTRACT: In order to make the output current wave shape of an inverter as nearly sinusoidal as possible, the resistance, inductance and capacitance of the load should be such that its natural frequency is near to the forced frequency imposed on the inverter by grid control; the commutation conditions will then also be right. If there is no need for the output current to be sinusoidal, in determining the commutating capacitance it is necessary to investigate the current wave form in the inverter load, see for example, Fig 1. If the inverter load current wave shape and the extinction time of the Valve are known, a value of capacitance may be chosen such that the anode potential of the valve passes through zero at the appropriate moment. However, inverters are often required to operate over a very wide range of frequencies ranging from hundreds of cycles to

Card  
1/3

80V/24-59-5-24/24

Calculation of the Commutating Capacitance and Cathode Inductance  
of a Parallel Inverter with Resistive Load

hundredths of cycles per second. At very low frequencies the current cannot be made sinusoidal by increasing the capacitance of the commutating capacitor. In this case the transformer connection of the inverters cannot be used and the bridge circuit is used, and it is then possible to calculate the value of the capacitance from analysis of the load current shape. This brief article describes a method of estimating the value of the commutating capacitance and the cathode inductance by another method that requires information only on the load resistance and the voltage of the d.c. source. The bridge inverter circuit with resistive load, shown diagrammatically in Fig 2, is considered. Eqs (1), (4) and (5) are derived from which the value of capacitance that is required for commutation may be calculated using Eq (6). This capacitance is calculated without allowing for the shunting effect of the load resistance which must be considered separately; formulae (6) - (9) are derived from which the final value of the commutating capacitance may be determined by Eq (10). Eq (12) is then derived

TITLE: Some Data on the Sounding by a Method of Electric  
Current Generated in the Ground, 2-

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geofizicheskaya  
1959, Nr 10, pp 1486-1491 (USSR)

ABSTRACT: An apparatus and the method of its application is described. The design of a receiving station is illustrated in Fig 1. It consists of a DC amplifier 1 (Fig 2), a cathode-ray oscillograph 2, whose screen is photographed during the setting up of a tension  $\Delta V$  in the receiver, and a pulse generator 3 (Fig 3). The measurements were carried out "in situ" and the curves of resistivity as a function of time,  $\tilde{\rho}_k(t)$ , were determined (Figs 4 to 6). The analysis of the curves showed that by this method a quantitative data of the geo-electric properties in a given cross-section can be determined. This method can be very economical if a fast plotting of graphs can be accomplished with the help of an electric computing machine. There are 6 figures and 2 Soviet references. ✓

AUTHOR: Ivanov, M. A. and Enenshteyn, B. S.  
TITLE: A non-inductive method of measuring amplitude and the phase of electric oscillations  
PERIODICAL: Akademiya nauk SSSR. Seriya geofizicheskaya. Izvestiya, no. 2, 1961, 245-250

TEXT: The method described is a particular application of pulse code modulation (PCM). The application is to field seismic exploration, where the problem of recording disturbances over a 100:1 range of amplitude or frequency has always been difficult to solve by conventional means e.g. by recorders or oscillograph photography. The principle may be understood from the block-schematic diagram of Fig. 1

Bx denotes the input signal

Card 1/3

22429

S/049/61/000/002/007/012  
D242/D301

A non-inductive method...

The sinusoidal signal is fed to an "amplitude transformer" 1, from which a train of pulses of fixed repetition rate and total number proportional to the signal amplitude is fed to the switch 3. Concurrently, the signal is rectified and dipped to give triggering pulses emerging from 2 to control the switch 3. This is to avoid false counts. Also the switch  $\Pi$  allows 3 to operate for a pre-determined number of periods, 1, 3, 5, or 10. Each time 3 is triggered by 2, the decade counter 4 counts the number of pulses. The decade counter 5 counts the number of times 3 is triggered. The whole process continues for the number of times  $\Pi$  is set to operate. This number is adjusted to suit the amplitudes expected and the accuracy required. In the case of a non-sinusoidal disturbance a kind of mean amplitude is recorded. The arrangement for phase measurement is shown in block schematic form in Fig. 2. Bx<sub>1</sub> is the input signal; Bx<sub>2</sub> is the reference signal. 1 and 2 converted the input and reference signals respectively into trains of displaced pulses. The displacement emerges from 3 as a square

Power supplies of +200, +150, +100 and -100 volts are used in addition to heaters. There are 10 figures.

TITLE: Station for frequency electromagnetic soundings

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 7, 1962, 33, abstract 7A215 (V sb. Vopr. teorii i praktiki elektrometrii, M., AN SSSR, 1961, 3-11)

TEXT: A frequency sounding station is described. It is intended for high-frequency amplitude and phase measurements over a wide range of frequencies and consists of a generating and a receiving set. Measurements are made in two cycles -- operating and calibrating. During the operating measurement cycle current of set frequency enters the power dipole AB from the generator, and the current's amplitude is recorded. Impulses of the current's initial phase are transmitted to the receiving set along an ultrashort-wave radio channel. The signal received by the electric or magnetic dipole MN is amplified and filtered from interference; then its amplitude and phase are recorded. The true magnitudes of the amplitudes and

Card 1/3

S/169/62/000/007/073/149  
D228/D307

Station for frequency ...

the phases of the signals received thereby remain unknown, since the amplification factor and the natural phase angle of the amplifying-recording channel are not known. These values are determined during the second calibration cycle of measurements. This consists of sending rectangular voltage of known amplitude with a frequency, strictly corresponding to that of the current in the dipole AB, from the output of the calibration apparatus to the input of the amplifying-recording channel. The circuits are given together with a description of the arrangement and the performance of the generating and receiving sets. The generator has a power of 33 kilowatts and operates in the frequency band 0.04 - 250 c/s. It is a thyatron commutator and gives out alternating current, whose amplitude and form depend chiefly on the resistance of line AB, the capacity of the commutating condenser, and the commutation frequency. The generating set is supplied from a gasoline A64-D/230 (AB4-D/230) unit with a power of 4 kilowatts, a voltage of 220 v, and a frequency of 50 c/s. The receiving set, as is pointed out, must ensure that the amplitudes and the phases can be measured very accurately (3 and 1% respectively). Since the signal received is strongly com-

Station for frequency ...

plicated by interference, a composite selective amplifier with a wide controllable transmission band and a high (about  $3 \times 10^8$ ) amplification factor is used to amplify the low (of the order of units and tens of  $\mu\text{V}$ ) reception signals and to filter them from interference. The chosen system of series filtration on aperiodic selective elements, distributed between several amplification stages, and the choice of amplification factors allows the time of transients in it to be reduced maximally. This is especially important when operating on infralow frequencies. The amplitude and the phase of the receiving signal are measured simultaneously by two mutually controlling methods: by means of an indicating instrument and through recording the signal on the film of a loop oscillograph. It is pointed out that tests of this station prototype have shown that it satisfies the requirements resulting from the method's theory and from the practice of field experimental research. TITLE: Generating set for frequency soundings

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 7, 1962, 34, abstract 7A220 (V sb. Vopr. teorii i praktiki elektrometrii, M., AN SSSR, 1961, 12-31)

TEXT: The generator set is intended for generating alternating currents with a frequency of 0.04 to 250 c/s. Current of up to 50 amp. is generated at an active load of 30 ohms. It is possible to get direct current of up to 100 amp. by employing a doubling circuit. The frequency and amplitude stability equals 1% over the whole range of 24 fixed frequencies. The equipment is mounted on a 3ИЛ (ZIL) vehicle in two sections -- equipmental and generating. The station's outfit also includes a special vehicle for winding and unwinding the wires. Direct current from ПН-45 (PN-45) generators is converted into alternating by a thyatron commutator. The thyatron commutator is a bridge circuit that guarantees almost

Generating set for ...

square current pulses at frequencies below 3 c/s. The form of the commutated current is substantially distorted as the frequency increases. The commutator is automatically switched on at a given d.c. voltage. A blocking device guarantees the connection system. A d.c. gasoline-set with a voltage of 220 v and a power of 4 kw is provided for supplying the station's electronic equipment. The station is controlled from a panel. The work of this station includes two cycles -- calibrating and measuring. The equipment described is acceptable for commercial utilization. [ Complete translation.]

SOURCE: AN SSSR. Doklady, v. 168, no. 4, 1966, 796-799

TOPIC TAGS: physical geology, electromagnetic wave

ABSTRACT:

This paper describes a method for the transformation of electromagnetic sounding curves, types K and Q. In this transformation method the interpreted curve, reflecting the cross section, in which the lower stratum has a finite resistance, is replaced by a curve reflecting this same cross section, but with a lower stratum having a specific resistance equal to zero. After such a transformation of the curves it is possible to make a quantitative interpretation and determine the values of the parameters.

SOURCE: AN SSSR. Doklady, v. 168, no. 5, 1966, 1052-1055

TOPIC TAGS: electromagnetic wave, telluric current, physical geology

ABSTRACT: The article cited below is a continuation and companion study to the paper abstracted above. The same method used in that study was used in the interpretation of three-layer electromagnetic frequency sounding curves of types A and H. However, it is shown that it is inadequate in this case to use the transformation method described. It also is necessary to take into account the property of symmetry of frequency soundings. The general method described in these two papers also is effective for interpreting magnetotelluric sounding curves. [This paper was presented by Academician A. V. Peyve on 23 Sep 65.] Orig. art. has: 2 figures and 2 formulas. [JPRS 37,397]

TITLE: On determining the energy radiated by earthquake foci in the form of seismic waves

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya geofizicheskaya, No. 10, 1961, 1472-1474

TEXT: The author derives equations for the energy flux in longitudinal and transverse waves from a source (e.g. an earthquake focus) in the form of a finite discontinuity surface  $\Sigma$ . The coordinate system,  $Oxyz$ , is selected so that the surface  $\Sigma$  coincides with the  $xz$ -plane. It is assumed that  $\Sigma$  is a circle of radius  $r$  whose center lies at the origin of coordinates. For an arbitrary displacement of particles at  $\Sigma$ , represented by an arbitrary Burgers vector  $\vec{b}$ , the author finds that the energy flux in longitudinal waves is given by:

Card 1/3

TITLE: Mechanism of the earthquake of May 31, 1959, with an epicenter in the Tecuchi region

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 10, 1962, 27, abstract 10A173 (Comun. Acad. RPR, 12, no. 3, 1962, 275-280 (Rum.; summaries in Rus. and Fr.))

TEXT: The mechanism of the earthquake of May 31, 1959, with an epicenter in the Tecuchi region and a depth  $h$  of 25-30 km, is investigated from its longitudinal waves. The first nodal plane has a NW-SE strike and a dip of  $55^{\circ}$ SW. The second nodal plane has a NE-SW direction and a dip of  $46^{\circ}$ SE. The tensile and intermediate stresses acted in a plane, having a N-NE-W-NW direction and a dip of  $25^{\circ}$ . The horizontal component of compression acted in a N-NE-S-SW direction.

TITLE: Concerning the kinematic and dynamic characteristics of secondary waves recorded during deep-seated earthquakes in Vrancea

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 1, 1963, 10, abstract 1067 (Comun. Acad, RPR., 1962, v. 12, no.4, 393-398 (Rum.: summary in Rus.))

TEXT: Kinematic and dynamic methods have up to now been used to determine the nature of three secondary waves observed between P and S waves during certain deep-seated earthquakes in Vrancea. Two different sets of results were obtained; thus according to the kinematic method these waves were pps, pss, and spp, while according to the dynamic method the waves were spps, sspp and sssp. The author discusses the reasons for this discrepancy and gives some supplementary kinematic and dynamic characteristics of these waves.

AUTHOR: Enescu, D.

TITLE: Mechanism of the origination of earthquakes and  
seismotectonic considerations

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 1, 1963, 11,  
abstract 1069 (Comun. Acad. RPR, 1962, v. 12, no. 6,  
609-622 (Rum.: summaries in Rus. and Eng.))

TEXT: The author investigates the mechanism of the origin  
of earthquakes observed on June 30, 1956 in the Black Sea, on Jan-  
uary 4, 1960 in the Rumanian lowlands, and on September 7 and Dec-  
ember 9, 1945 in the Carpathians. The data indicate a certain de-  
gree of correlation between the mechanisms of the origination of  
these four earthquakes. The most important conclusion appears to  
be that in all four cases the direction of one of the nodal planes  
was NW-SE, and this coincided with the direction of the line connec-  
ting the epicenters of these earthquakes. This led to the conclu-  
sion that the above nodal plane coincided with the fault plane, and

Card 1/2

Mechanism of the origination ...

S/169/63/000/001/031/062  
D263/D307

that the earthquakes occurred in the fault plane intersecting Rumanian territory from SE to NW, passing near the fold of the Carpathian arc. This result is in agreement with the geologists who postulated the existence of such an extensive fault-plane, with which are connected the volcanic eruptions in the Keliman-Khergits massif. In the Black Sea earthquake the compressive stresses acted almost horizontally and perpendicularly to the coast. In the earthquakes of January 4, 1960 and December 7, 1957 [Abstracter's note: September?], the compressive stresses acted in a direction parallel to the southern arm of the Carpathian arc, while during the December 9, 1945 quake these stresses acted in parallel to the tangent to the fold of the Carpathian arc.
